**Tick ID**

**BLACKLEGGED TICK**
*Ixodes scapularis*

*Where found:* Widely distributed in the northeastern and upper midwestern United States.

*Transmits:* Lyme disease, anaplasmosis, babesiosis, and Powassan disease.

*Comments:* The greatest risk of being bitten exists in the spring, summer and fall. However, adults may be out searching for a host any time winter temperatures are above freezing. Stages most likely to bite humans are nymphs and adult females.

**AMERICAN DOG TICK**
*Dermacentor variabilis*

*Where found:* Widely distributed east of the Rocky Mountains. Also occurs in limited areas on the Pacific Coast.

*Transmits:* Tularemia and Rocky Mountain spotted fever.

*Comments:* The highest risk of being bitten occurs during spring and summer. Dog ticks are sometimes called wood ticks. Adult females are most likely to bite humans.

**LONE STAR TICK**
*Amblyomma americanum*

*Where found:* Widely distributed in the southeastern and eastern United States.

*Transmits:* *Ehrlichia chaffeensis* and *Ehrlichia ewingii* (which cause human ehrlichiosis), tularemia, and STARI.

*Comments:* A very aggressive tick that bites humans. The adult female is distinguished by a white dot or “lone star” on her back. Lone star tick saliva can be irritating; redness and discomfort at a bite site does not necessarily indicate an infection. The nymph and adult females most frequently bite humans and transmit disease.

---

**NOTE:** Illustrations are not to scale.
**BROWN DOG TICK**  
*Rhipicephalus sanguineus*

**Where found:** Worldwide.

**Transmits:** Rocky Mountain spotted fever (in the southwestern U.S. and along the U.S.-Mexico border).

**Comments:** Dogs are the primary host for the brown dog tick in each of its life stages, but the tick may also bite humans or other mammals.

---

**GROUNDHOG TICK**  
*Ixodes cookei*

**Where found:** Throughout the eastern half of the U.S. and Canada.

**Transmits:** Powassan disease.

**Comments:** Also called woodchuck ticks. All life stages feed on a variety of warm-blooded animals, including groundhogs, skunks, squirrels, raccoons, foxes, weasels, and occasionally people and domestic animals.

---

**GULF COAST TICK**  
*Amblyomma maculatum*

**Where found:** Coastal areas of the U.S. along the Atlantic coast and the Gulf of Mexico.

**Transmits:** *Rickettsia parkeri* rickettsiosis, a form of spotted fever.

**Comments:** Larvae and nymphs feed on birds and small rodents, while adult ticks feed on deer and other wildlife. Adult ticks have been associated with transmission of *R. parkeri* to humans.

---

**ROCKY MOUNTAIN WOOD TICK**  
*Dermacentor andersoni*

**Where found:** Rocky Mountain states and southwestern Canada from elevations of 4,000 to 10,500 feet.

**Transmits:** Rocky Mountain spotted fever, Colorado tick fever, and tularemia.

**Comments:** Adult ticks feed primarily on large mammals. Larvae and nymphs feed on small rodents. Adult ticks are primarily associated with pathogen transmission to humans.

---

**SOFT TICK**  
*Ornithodoros spp.*

**Where found:** Throughout the western half of the U.S. and southwestern Canada.

**Transmits:** Tick-borne relapsing fever (*Borrelia hermsii, B. parkeri, or B. turicatae*)

**Comments:** Humans typically come into contact with soft ticks when they sleep in rodent infested cabins. The ticks emerge at night and feed briefly while the person is sleeping. The bites are painless, and most people are unaware that they have been bitten.

---

**WESTERN BLACKLEGGED TICK**  
*Ixodes pacificus*

**Where found:** Along the Pacific coast of the U.S., particularly northern California.

**Transmits:** Anaplasmosis and Lyme disease.

**Comments:** Nymphs often feed on lizards, as well as other small animals. As a result, rates of infection are usually low (~1%) in the adult, the stage most likely to bite humans.
Overview of Tickborne Diseases

Selected Tickborne Diseases Reported to CDC, U.S., 2011

- Anaplasmosis
- Babesiosis
- Ehrlichiosis
- Lyme Disease
- Rocky Mountain Spotted Fever
- Tularemia

**NOTE:** Each dot represents one case. Cases are reported from the infected person’s county of residence, not necessarily the place where they were infected.

**NOTE:** During 2011, babesiosis was reportable in Alabama, California, Connecticut, Delaware, Indiana, Maine, Maryland, Massachusetts, Minnesota, Nebraska, New Hampshire, New Jersey, New York, North Dakota, Oregon, Rhode Island, Tennessee, Vermont, Washington, and Wisconsin. CDC was not notified through the national surveillance system of cases in other states.

**NOTE:** In 2011, Alaska reported 8 travel-related cases of Lyme disease. No other cases of tickborne illness were reported from Alaska or Hawaii.
Anaplasmosis

WHERE FOUND
Anaplasmosis is most frequently reported from the upper midwest and northeastern U.S. in areas that correspond with the known geographic distribution of Lyme disease.

AGENT
Anaplasma phagocytophilum

INCUBATION PERIOD: 1–2 weeks

SIGNS AND SYMPTOMS
- Fever, chills
- Severe headache
- Malaise
- Myalgia
- Gastrointestinal symptoms (nausea, vomiting, diarrhea, anorexia)
- Cough
- Rash (rare cases)
- Stiff neck*
- Confusion*

* May present later (5 days after onset of symptoms) and may be prevented by early treatment.

LABORATORY CONFIRMATION
Antibodies to A. phagocytophilum are detectable 7–10 days after illness onset. The gold-standard serologic test looks for a four-fold change in antibody titers using immunofluorescence assay (IFA) on paired samples. The first sample should be taken within the first week of illness and the second should be taken 2 to 4 weeks later.

- Demonstration of a four-fold change in IgG-specific antibody titer by immunofluorescence assay (IFA) test in paired serum samples; or
- Detection of DNA by PCR of whole blood. This method is most sensitive within the first week of illness; sensitivity may decrease after administration of antibiotics.

NOTE: IgM antibodies are less specific than IgG antibodies and are more likely to generate false positives. IgM results alone should not be used for laboratory diagnosis.

NOTE: Consider the possibility of coinfection with Babesia microti and/or Borrelia burgdorferi.

NOTE: Antibody titers are frequently negative in the first 7–10 days of illness, thus serologic tests may be falsely negative during this time period.
Anaplasmosis, ehrlichiosis, and Rocky Mountain spotted fever are treated in the same manner with doxycycline. Clinical suspicion of any of these diseases is sufficient to begin treatment. Delay in treatment may result in severe illness and even death. The regimens listed below are guidelines only and may need to be adjusted depending on a patient’s age, medical history, underlying health conditions, pregnancy status, or allergies. Consult an infectious disease specialist in cases of documented pregnancy or life-threatening allergies to doxycycline.

<table>
<thead>
<tr>
<th>AGE CATEGORY</th>
<th>DRUG</th>
<th>DOSAGE</th>
<th>MAXIMUM</th>
<th>DURATION (DAYS)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adults</td>
<td>Doxycycline</td>
<td>100 mg twice per day, orally or IV</td>
<td>100 mg/dose</td>
<td>Patients with suspected anaplasmosis infection should be treated with doxycycline for 10-14 days to provide appropriate length of therapy for possible incubating co-infection with Lyme disease</td>
</tr>
<tr>
<td>Children weighing &lt;100 lbs. (45.4 kg)</td>
<td>Doxycycline</td>
<td>2.2 mg/kg per dose twice per day, orally or IV</td>
<td>100 mg/dose</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE:** Use doxycycline as first-line treatment for suspected anaplasmosis in patients of all ages. The use of doxycycline to treat suspected anaplasmosis in children is recommended by both the CDC and the American Academy of Pediatrics Committee on Infectious Diseases. Use of antibiotics other than doxycycline increases the risk of patient death. At the recommended dose and duration needed to treat anaplasmosis, no evidence has been shown to cause staining of permanent teeth, even when five courses are given before the age of eight.

Babesiosis

WHERE FOUND
Babesiosis is most frequently reported from the northeastern and upper midwestern United States in areas where Babesia microti is endemic. Sporadic cases of infection caused by novel Babesia agents have been detected in other U.S. regions, including the West Coast. In addition, transfusion-associated cases of babesiosis can occur anywhere in the country.

AGENT
Babesia microti and other Babesia species

INCUBATION PERIOD: 1–9+ weeks

SIGNS AND SYMPTOMS
- Fever, chills, sweats
- Malaise, fatigue
- Myalgia, arthralgia, headache
- Gastrointestinal symptoms, such as anorexia and nausea (less common: abdominal pain, vomiting)
- Dark urine
- Less common: cough, sore throat, emotional lability, depression, photophobia, conjunctival injection
- Mild splenomegaly, mild hepatomegaly, or jaundice may occur in some patients

NOTE: Not all infected persons are symptomatic or febrile. The clinical manifestations, if any, usually develop within several weeks after the exposure but may develop or recur months later (for example, in the context of surgical splenectomy).

GENERAL LABORATORY FINDINGS
- Decreased hematocrit due to hemolytic anemia
- Thrombocytopenia
- Elevated serum creatinine and blood urea nitrogen (BUN) values
- Mildly elevated hepatic transaminase values

NOTE: If the diagnosis of babesiosis is being considered, manual (nonautomated) review of blood smears should be requested explicitly. In symptomatic patients with acute infection, Babesia parasites typically can be detected by blood-smear examination, although multiple smears may need to be examined. Sometimes it can be difficult to distinguish between Babesia and malaria parasites and even between parasites and artifacts (such as stain or platelet debris). Consider having a reference laboratory confirm the diagnosis and the species. In some settings, molecular techniques can be useful for detecting and differentiating among Babesia species.

NOTE: Antibody detection by serologic testing can provide supportive evidence for the diagnosis but does not reliably distinguish between active and prior infection.

LABORATORY DIAGNOSIS
- Identification of intraerythrocytic Babesia parasites by light-microscopic examination of a peripheral blood smear; or
- Positive Babesia (or B. microti) polymerase chain reaction (PCR) analysis; or
- Isolation of Babesia parasites from a whole blood specimen by animal inoculation (in a reference laboratory).

SUPPORTIVE LABORATORY CRITERIA
- Demonstration of a Babesia-specific antibody titer by indirect fluorescent antibody (IFA) testing for total immunoglobulin (Ig) or IgG.

Babesiosis is caused by parasites that infect red blood cells. Most U.S. cases are caused by Babesia microti, which is transmitted by Ixodes scapularis ticks, primarily in the Northeast and upper Midwest. Babesia parasites also can be transmitted via transfusion, anywhere, at any time of the year. To date, no Babesia tests have been licensed for screening blood donors. Congenital transmission also has been reported.

Babesia infection can range from asymptomatic to life threatening. Risk factors for severe babesiosis include asplenia, advanced age, and impaired immune function. Severe cases can be associated with marked thrombocytopenia, disseminated intravascular coagulation, hemodynamic instability, acute respiratory distress, renal failure, hepatic compromise, altered mental status, and death.
Treatment decisions and regimens should consider the patient’s age, clinical status, immunocompetence, splenic function, comorbidities, pregnancy status, other medications, and allergies. Expert consultation is recommended for persons who have or are at risk for severe or relapsing infection or who are at either extreme of age. For ill patients, babesiosis usually is treated for at least 7–10 days with a combination of two medications—typically, either atovaquone PLUS azithromycin; OR clindamycin PLUS quinine (this combination is the standard of care for severely ill patients). The typical regimens for adults are provided in the table below.

<table>
<thead>
<tr>
<th>AGE CATEGORY</th>
<th>DRUG</th>
<th>DOSAGE</th>
<th>MAXIMUM</th>
<th>DURATION (DAYS)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adults</td>
<td>Atovaquone</td>
<td>750 mg orally every 12 hours</td>
<td>N/A</td>
<td>7–10</td>
</tr>
<tr>
<td>Prescribe together</td>
<td>Azithromycin</td>
<td>On the first day, give a total dose in the range of 500–1000 mg orally; on subsequent days, give a total daily dose in the range of 250–1000 mg*</td>
<td>1000 mg per day</td>
<td>7–10</td>
</tr>
<tr>
<td>Adults</td>
<td>Clindamycin**</td>
<td>300–600 mg IV every 6 hours OR 600 mg orally every 8 hours**</td>
<td>N/A</td>
<td>7–10</td>
</tr>
<tr>
<td>Prescribe together</td>
<td>Quinine**</td>
<td>650 mg orally every 6–8 hours</td>
<td>N/A</td>
<td>7–10</td>
</tr>
</tbody>
</table>

* The upper end of the range (600–1000 mg per day) has been used for adults who are immunocompromised.

** The standard of care for patients with severe babesiosis (e.g., with parasitemia levels ≥10% and/or organ-system dysfunction) is quinine plus clindamycin; typically, the clindamycin is administered intravenously. Such patients also might require or benefit from exchange transfusions, vasopressor therapy, mechanical ventilation, or dialysis.

NOTE: Most persons without clinical manifestations of infection do not require treatment. However, consider treating persons who have had demonstrable parasitemia for more than 3 months.

REFERENCES

Ehrlichiosis

WHERE FOUND
Ehrlichiosis is most frequently reported from the southeastern and south-central U.S., from the eastern seaboard extending westward to Texas. The areas from which cases are reported correspond with the known geographic distribution of the lone star tick (*Amblyomma americanum*), which is associated with transmission of both *E. chaffeensis* and *E. ewingii*. Three states (Oklahoma, Missouri, Arkansas) account for 35% of all reported *E. chaffeensis* infections.

INCUBATION PERIOD: 1–2 weeks

SIGNS AND SYMPTOMS

- Fever
- Headache
- Chills
- Malaise
- Muscle pain
- Gastrointestinal symptoms (nausea, vomiting, diarrhea, anorexia)
- Confusion
- Conjunctival injection
- Rash (in up to 60% of children, less than 30% of adults)

The above list presents symptoms commonly seen with ehrlichiosis. However, it is important to note that few people will develop all symptoms and the number and combination of symptoms varies greatly from person to person.

Confirmation of the diagnosis is based on laboratory testing, but antibiotic therapy should not be delayed in a patient with a suggestive clinical presentation.

GENERAL LABORATORY FINDINGS
Typically Observed During the First Week of Clinical Disease:

- Mild anemia
- Thrombocytopenia
- Leukopenia (characterized by relative and absolute lymphopenia and a left shift)
- Mild to moderate elevations in hepatic transaminases may occur in some patients
- During the acute stage of illness, morulae may be detected in about 20% of patients. *E. chaffeensis* most commonly infects monocytes, whereas *E. ewingii* more commonly infects granulocytes.

LABORATORY CONFIRMATION

Antibodies to *Ehrlichia* are detectable 7–10 days after illness onset. The gold-standard serologic test looks for a four-fold change in IgG-specific antibody titers using immunofluorescence assay (IFA) test on paired samples. The first sample should be taken within the first week of illness and the second should be taken 2 to 4 weeks later.

- Demonstration of a four-fold change in IgG-specific antibody titer by immunofluorescence assay (IFA) test in paired serum samples; or
- Detection of DNA by PCR on whole blood. This method is most sensitive within the first week of illness; may decrease in sensitivity after administration of antibiotics.

NOTE: IgM antibodies are less specific than IgG antibodies and are more likely to generate false positive results. IgM results alone should not be used for laboratory diagnosis.

NOTE: Antibody titers are frequently negative in the first 7–10 days of illness, thus serologic tests may be falsely negative during this time period.
Anaplasmosis, ehrlichiosis and Rocky Mountain spotted fever are treated in the same manner with doxycycline. Clinical suspicion of any of these diseases is sufficient to begin treatment. Delay in treatment may result in severe illness and death. The regimens listed below are guidelines only and may need to be adjusted depending on a patient’s age, medical history, underlying health conditions, pregnancy status, or allergies. Consult an infectious disease specialist in cases of documented pregnancy or life-threatening allergies to doxycycline.

LYME DISEASE OR STARI?

An erythema migrans rash has also been described in humans following bites of the lone star tick, Amblyomma americanum. This condition has been named Southern Tick-Associated Rash Illness (STARI). Although the rash may be accompanied by flu-like symptoms, long-term sequelae have not been reported. Because the cause of STARI is unknown, diagnostic blood tests are not available.

Lone star ticks can be found from central Texas and Oklahoma eastward across the southern states and along the Atlantic coast as far north as Maine.

It is not known whether antibiotic treatment is necessary or beneficial for patients with STARI. Nevertheless, because STARI resembles early Lyme disease, physicians often treat patients with the same antibiotics recommended for Lyme disease.

NOTE: Coinfection with B. microti and/or A. phagocytophilum should be considered in patients who present with initial symptoms that are more severe than are commonly observed with Lyme disease alone, especially in those who have high-grade fever for more than 48 hours despite appropriate antibiotic therapy or who have unexplained leukopenia, thrombocytopenia, or anemia. Coinfection might also be considered in patients whose erythema migrans skin lesion has resolved but have persistent flu-like symptoms.
Lyme Disease

**AGENT**

*Borrelia burgdorferi*

REFERENCES

NOTE: For patients intolerant of amoxicillin, doxycycline, and cefuroxime axetil, the macrolides azithromycin, clarithromycin, or erythromycin may be used, although they have a lower efficacy. Patients treated with macrolides should be closely observed to ensure resolution of clinical manifestations.

Patients treated with macrolides should be closely observed to ensure resolution of clinical manifestations.

REFERENCES

The erythema migrans (EM) rash occurs in 70–80% of patients with Lyme disease. EM rashes expand slowly over a few days after which they may develop a “bull’s-eye” appearance consisting of a red ring with central clearing. However, EM may take alternate forms—solid lesions, blue-purple hues, and crusted or blistering lesions have all been documented. The rash is not painful or pruritic, but it may be warm to the touch. If early localized Lyme disease is not treated, patients may develop multiple secondary circular rashes as spirochetes disseminate throughout the body.

**Special thanks to DermAtlas for providing the photographs.**
**Rocky Mountain Spotted Fever**

**WHERE FOUND**

Although Rocky Mountain spotted fever cases have been reported throughout most of the contiguous U.S., five states (North Carolina, Oklahoma, Arkansas, Tennessee, and Missouri) account for over 60% of RMSF cases.

Rocky Mountain spotted fever has become increasingly common in certain areas of Arizona over the last several years. Between 2003 and 2012 over 250 cases and 19 fatalities occurred. RMSF can be rapidly fatal if not treated within the first 5 days of symptoms. Before tetracycline antibiotics were available, case fatality rates ranged from 20–80%.

**INCUBATION PERIOD:** 2–14 days

**SIGNS AND SYMPTOMS**

- Fever, chills
- Severe headache
- Malaise
- Myalgia
- Gastrointestinal symptoms (nausea, vomiting, anorexia, abdominal pain, diarrhea, abdominal tenderness)
- Cough
- Conjunctival injection, ± photophobia
- Altered mental status
- Focal neurologic deficits, including cranial or peripheral motor nerve paralysis or sudden transient deafness

**Maculopapular Rash**

- Typically appears 2–5 days after the onset of fever
- Small, flat, pink, non-itchy spots (macules) initially appear on the wrists, forearms, and ankles then spread to the trunk and sometimes palms and soles.
- Rash may not develop until late in the disease process, after treatment should have already begun. Approximately 10% of RMSF patients never develop a rash at all.

- Consider RMSF if other signs and symptoms support a diagnosis, even if a rash is not present.

**Petechial Rash**

- Red to purple spots (petechiae) are usually not seen until day 6 or later after onset of symptoms.
- Petechial rash is considered a sign of progression to severe disease. Every attempt should be made to begin treatment before petechiae develop.

**NOTE:** Neurologic symptoms are typically not seen until later in the disease progression and may be prevented with early treatment.

**Confirmation of the diagnosis is based on laboratory testing, but antibiotic therapy should not be delayed in a patient with a suggestive clinical presentation. Antibiotics are less likely to prevent fatal outcome from RMSF if started after day 5 of symptoms.**

**GENERAL LABORATORY FINDINGS**

- Thrombocytopenia
- Mildly elevated hepatic transaminase levels
- Hyponatremia

**LABORATORY CONFIRMATION**

Antibodies to *R. rickettsii* are detectable 7–10 days after illness onset. The gold-standard serologic test looks for a four-fold change in antibody titers using immunofluorescence assay (IFA) on paired samples. The first sample should be taken within the first week of illness and the second should be taken 2 to 4 weeks later.

- Demonstration of a four-fold change in IgG-specific antibody titer by immunofluorescence assay (IFA) test in paired serum samples; or
- Detection of DNA in a skin biopsy of rash by polymerase chain reaction (PCR) assay (generally unreliable for acute blood samples).
- Immunohistochemical (IHC) staining of organism

**NOTE:** IgM antibodies are less specific than IgG antibodies and are more likely to generate false positives. IgM results alone should not be used for laboratory diagnosis.

**NOTE:** Antibody titers are frequently negative in the first 7–10 days of illness, thus serologic tests may be falsely negative during this time period.
Anaplasmosis, ehrlichiosis and Rocky Mountain spotted fever are treated in the same manner with doxycycline.† Clinical suspicion of any of these diseases is sufficient to begin treatment. Delay in treatment may result in severe illness and even death. The regimens listed below are guidelines only and may need to be adjusted depending on a patient’s age, medical history, underlying health conditions, pregnancy status, or allergies. Consult an infectious disease specialist in cases of pregnancy or documented life-threatening allergies to doxycycline.

Tularemia
Francisella tularensis

WHERE FOUND
In the U.S., naturally occurring tularemia infections have been reported from all states except Hawaii. Ticks that transmit tularemia to humans include the dog tick (Dermacentor variabilis), the wood tick (Dermacentor andersoni), and the lone star tick (Amblyomma americanum). Other transmission routes include inhalation and direct inoculation.

INCUBATION PERIOD:
3–5 days (range 1–21 days)

NOTE: The clinical presentation of tularemia will depend on a number of factors, including the portal of entry.

SIGNs AND SYMPTOMs
• Fever, chills
• Headache
• Malaise, fatigue
• Anorexia
• Myalgia
• Chest discomfort, cough
• Sore throat
• Vomiting, diarrhea
• Abdominal pain

(Ulcero) Glandular
• Localized lymphadenopathy
• Cutaneous ulcer at infection site (not always present)

Oculoglandular
• Photophobia
• Excessive lacrimation
• Conjunctivitis
• Preauricular, submandibular and cervical lymphadenopathy

Oropharyngeal
• Severe throat pain
• Cervical, preporatid, and/or retropharyngeal lymphadenopathy

Pneumonic
• Non-productive cough
• Substernal tightness
• Pleuritic chest pain
• Hilar adenopathy, infiltrate, or pleural effusion may be present on chest X-ray

Typhoidal
• Characterized by any combination of the general symptoms (without localizing symptoms of other syndromes)

GENERAL LABORATORY FINDINGS
• Leukocyte count and sedimentation rate may be normal or elevated
• Thrombocytopenia
• Hyponatremia
• Elevated hepatic transaminases
• Elevated creatine phosphokinase
• Myoglobinuria
• Sterile pyuria

LABORATORY DIAGNOSIS
• Demonstration of a four-fold change in antibody titer in paired sera; or
• Isolation of organism from a clinical specimen; or
• Detection of organism by immunofluorescence assay (IFA) test or a single elevated serum antibody titer is supportive of the diagnosis; however, a single antibody titer should be confirmed by either one of the methods above.
The regimens listed below are guidelines only and may need to be adjusted depending on a patient’s age, medical history, underlying health conditions, pregnancy status or allergies. Consult an infectious disease specialist for the most current treatment guidelines or for individual patient treatment decisions.

*Not a U.S. FDA-approved use, but has been used successfully to treat patients with tularemia.

**NOTE:** Gentamicin or streptomycin is preferred for treatment of severe tularemia. Doses of both streptomycin and gentamicin should be adjusted for renal insufficiency.

**NOTE:** Chloramphenicol may be added to streptomycin to treat meningitis.

**REFERENCES**

**Colorado Tick Fever (CTF)**

**WHERE FOUND** The geographic range of Colorado tick fever virus includes the western United States and southwestern Canada at elevations 4,000 to 10,000 feet. Cases occur primarily in Colorado, Utah, Montana, and Wyoming. Although rare, the virus can also be transmitted from person-to-person via blood transfusion.

**INCUBATION PERIOD:** 1-14 days

**SIGNS AND SYMPTOMS**
- Fever, chills, headache, myalgias, and lethargy
- ~50% of patients have a biphasic illness with symptoms remitting after 2 to 4 days, but then recurring 1 to 3 days later
- Conjunctival injection, pharyngeal erythema and lymphadenopathy may be present
- Maculopapular or petechial rash in <20% of patients
- Prolonged convalescence characterized by weakness and fatigue is common in adults

**GENERAL LABORATORY FINDINGS**
- Life-threatening complications and death are rare and usually associated with disseminated intravascular coagulation or meningoencephalitis in children

**LABORATORY DIAGNOSIS**
- Culture and RT-PCR during first 2 weeks of illness
- Serologic assays (e.g., IgM-capture EIA, indirect fluorescent antibody, and plaque-reduction neutralization) on convalescent samples. IgM antibodies usually do not appear until 14–21 days after illness onset.

**TREATMENT**
- No specific antiviral treatment is available. Patients with suspected CTF should receive supportive care as appropriate. Patients with confirmed CTF should defer blood and bone marrow donation for at least 6 months after recovery.

**REFERENCES**

**Tickborne Relapsing Fever (TBRF)**

**WHERE FOUND** In the U.S., TBRF occurs most commonly in 14 western states: Arizona, California, Colorado, Idaho, Kansas, Montana, Nevada, New Mexico, Oklahoma, Oregon, Texas, Utah, Washington, and Wyoming. Most cases occur in the summer when people vacation and sleep in rodent-infested cabins. However, TBRF can also occur in the winter months when fires started to warm a cabin activate ticks resting in the walls and woodwork.

**INCUBATION PERIOD:** ~7 days, followed by recurring febrile episodes that last ~3 days and are separated by afebrile periods of ~7 days

**SIGNS AND SYMPTOMS**
- Headache
- Myalgia
- Chills
- Nausea, vomiting
- Arthralgia

**COMMON FINDINGS ON ROUTINE LABORATORY TESTS**
- Normal to increased white blood cell count with a left shift
- Mildly increased serum bilirubin
- Mild to moderate thrombocytopenia

**LABORATORY DIAGNOSIS**
- Elevated erythrocyte sedimentation rate
- Slightly prolonged prothrombin time (PT) and partial thromboplastin time (PPT)
- Observation of *Borrelia* spirochetes in smears of peripheral blood, bone marrow, or CSF
- Organsms are best detected in blood obtained while a person is febrile
- Serologic testing for TBRF is not standardized and results may vary by laboratory

**TREATMENT**
- Tetracycline 500 mg every 6 hours for 10 days is the preferred oral regimen for adults. If tetracyclines are contraindicated, an effective alternative is erythromycin 500 mg (or 12.5 mg/kg) every 6 hours for 10 days.
- For CNS involvement, ceftriaxone 2 g per day for 10–14 days is preferred.
- When initiating antibiotic therapy, all patients should be observed during the first 4 hours of treatment for a Jarisch-Herxheimer reaction.
- Acute respiratory distress syndrome requiring intubation has occurred in several patients undergoing TBRF treatment.

Other Tickborne Diseases

Powassan Disease

**WHERE FOUND**: Powassan virus infections have been recognized in the United States, Canada and Russia. In the United States, cases have been reported primarily from northeastern states and the Great Lakes region.

**INCUBATION PERIOD**: 1 to 4 weeks

**SIGNS AND SYMPTOMS**
- Fever, headache, vomiting, and generalized weakness
- Usually progresses to meningoencephalitis. May include meningeal signs, altered mental status, seizures, aphasia, paresis, movement disorders, or cranial nerve palsies

**LABORATORY FINDINGS**
- CSF findings include lymphocytic pleocytosis (neutrophils can predominate early), normal or mildly elevated protein, and normal glucose

**LABORATORY DIAGNOSIS**
- No commercially-available tests; testing available at CDC and selected state health departments.
- Measurement of virus-specific IgM antibodies in serum or cerebrospinal fluid (CSF). Cross-reaction with other flaviviruses (e.g., West Nile, dengue, or St. Louis viruses) can occur; plaque reduction neutralization tests should be performed to confirm the diagnosis.
- RT-PCR may detect viral RNA in acute CSF specimens or tissues but the sensitivity is unknown and this method should not be used to rule out the diagnosis.

**TREATMENT**
- No specific antiviral treatment for Powassan disease is available. Patients with suspected Powassan disease should receive supportive care as appropriate.

Tickborne Diseases Abroad

Activities that increase risk for tick exposure worldwide include (but are not limited to): outdoor recreation such as camping, hiking, fishing, or bicycling; military training; outdoor occupations such as forestry; and collecting mushrooms, berries, or flowers in forested or agricultural areas.

Tick Bites/Prevention

Ticks are generally found near the ground, in brushy or wooded areas. They can’t jump or fly. Instead, they climb tall grasses or shrubs and wait for a potential host to brush against them. When this happens, they climb onto the host and seek a site for attachment.

PREVENTION
1. Wear repellent containing at least 20% DEET or permethrin-treated clothing.
2. Treat dogs for ticks.
3. Check for ticks daily.
4. Shower soon after being outdoors.

TICK REMOVAL
1. Use fine-tipped tweezers to grasp the tick as close to the skin’s surface as possible.
2. Pull upward with steady, even pressure. Don’t twist or jerk the tick; this can cause the mouth-parts to break off and remain in the skin. If this happens, remove the mouth-parts with clean tweezers. If you are unable to remove the mouth parts easily, leave them alone and let the skin heal.
3. After removing the tick, thoroughly clean the bite area and your hands with rubbing alcohol, an iodine scrub, or soap and water.

TICK BITE PROPHYLAXIS
The Infectious Disease Society of America (IDSA) does not generally recommend antimicrobial prophylaxis for prevention of Lyme disease after a recognized tick bite. However, in areas that are highly endemic for Lyme disease, a single dose of doxycycline may be offered to adult patients (200 mg) who are not pregnant and to children older than 8 years of age (4 mg/kg up to a maximum dose of 200 mg) when all of the following circumstances exist:

a. The attached tick can be reliably identified as an adult or nymphal I. scapularis tick that is estimated to have been attached for ≥36 hours based on the degree of engorgement of the tick with blood or likely time of exposure to the tick;
b. Prophylaxis can be started within 72 hours of the time that the tick was removed;
c. Ecologic information indicates that the local rate of infection of I. scapularis with B. burgdorferi is ≥20%; and
d. Doxycycline is not contraindicated.

Antibiotic treatment following a tick bite is not recommended as a means to prevent anaplasmosis, babesiosis, ehrlichiosis, or Rocky Mountain spotted fever. There is no evidence this practice is effective, and it may simply delay onset of disease. Instead, persons who experience a tick bite should be alert for symptoms suggestive of tickborne illness and consult a physician if fever, rash, or other symptoms of concern develop.

Tularemia prophylaxis is recommended only in cases of laboratory exposure to infectious materials:
• Doxycycline (100 mg orally BID X 14 days) is generally recommended for prophylaxis in adults.
• Ciprofloxacin (500 mg orally BID) is not FDA-approved for prophylaxis of tularemia but has demonstrated efficacy in various studies, and may be an alternative for patients unable to take doxycycline.
Based on “Tickborne Diseases in Massachusetts: A Physician’s Reference Manual”, produced by collaboration between MDPH, Nancy Shadick, MD, MPH, and Nancy Maher, MPH of the RBB Arthritis and Musculoskeletal Diseases Clinical Research Center at Brigham and Women’s Hospital and Dennis Hoak, MD, of Martha’s Vineyard Hospital.
